The ability of a cell to respond to a particular cytokine is determined by the particular combination of cell surface receptors that it possesses. The response to the cytokine can be mediated by the activation of the intracellular pathways, such as the JAK/STAT pathway, which affects the transcription of genes that control cell cycle progression, angiogenesis, cell migration and apoptosis. These responses can have profound effects on the physiology of the cell, including cell division, differentiation, and death. A number of cytokines, including erythropoietin, granulocyte-macrophage colony-stimulating factor (GM-CSF), and IL-2 have been demonstrated to be useful in the treatment of anemia, cancer, and immune deficiencies, respectively. In general, the mechanism of action of these cytokines involves activation of the JAK/STAT pathway. When activated, the receptor tyrosine kinases on the surface of the cell activate the JAK2 kinase that, in turn, initiates the tyrosine phosphorylation of STATs. STATs are phosphorylated on a single tyrosine, and this induces the dimerization of the STATs and their translocation to the nucleus. The dimers of the phosphorylated STATs bind to sites on DNA, which, in turn, lead to the transcription of a particular gene. IL-2 and other cytokines are currently being used to treat a variety of conditions, including mal a1d647c40b
