The manufacture of miniature circuits normally requires the fabrication of a relatively large number of different circuit boards. This is necessary because a single circuit board usually houses a relatively small number of circuits. The circuits are commonly mounted on one or more ceramic circuit devices. The ceramic devices may be mounted on separate ceramic circuit device carriers or on a single ceramic circuit device carrier. The ceramic circuit devices are typically supported on a circuit board by a mounting structure. The mounting structure is commonly formed by a plurality of mounting pads which are formed on the circuit board. The ceramic circuit device is supported by the mounting pads in the manner described in U.S. Pat. Nos. 4,427,928 and 4,505,784, for example. The mounting pads must be accurately formed and must be accurately aligned with the circuit paths of the circuit board to be effectuated. These mounting pads take up space on the board which is undesirable. Furthermore, electrical energy is transferred from one ceramic circuit device to another ceramic circuit device using wire bonds. The wire bonds commonly extend through apertures in the circuit board and are soldered to a terminal on the other circuit device. The bond joint between the circuit device and the circuit board must be sufficiently strong to withstand the typical stresses on the board-mounted ceramic circuit device. Therefore, there is a need for a mounting structure which can be accurately formed and accurately aligned with the circuit paths on a circuit board without taking up unnecessary space on the board. There is also a need for a structure which can be used to provide a strong mechanical bond between a ceramic circuit device and a circuit board.The flash development process is simple. Imagine that you are playing a game of chess or reading. While your eyes are locked to the printed page or the game board, the subconscious mind is busily taking notes. These notes become vague thoughts, and they create ideas which motivate your imagination. These ideas are then translated into subconscious thoughts, and the thoughts are transmuted into quickened mental images, which are then translated into emotions, and then translated into expression. The actual process of translating thoughts into images is called "visualization", and this process is fun. You simply imagine something in your mind's eye
